

For the best of reasons

Decoding the August Complex Fire: Investigating the Atmospheric and Surface Characteristics Driving One of California's Largest Wildfires

Lead: Taylor Grace, Global Climate Change
Postdoctoral Fellow

Contributors: Tracy Mallard, Sarah Medepalli

Motivation

- Dry, hot, and windy conditions are known to be primary conditions for ignition and spreading of wildfires
- Increasing trend in wildfire frequency and size across the western United States (Westerling et al., 2006; Dennison et al., 2014; Weber and Yadav, 2020)
- Many models (e.g., Fast Fuels, QUIC-Fire, Wildfire Digital Twin model, etc.) are mostly utilized for modeling active-fire behaviors
- Responding to wildland fires requires extensive collaborations so as much warning prior to an extreme event may lower costs, resources, and mitigate damages

August Complex Fire: Background

- Start Date: August 16, 2020
- End Date: November 11, 2020
- Total Acres Burned: 1,032,648
- Estimated Damage Cost: \$115 million US

Weather Regimes Methods

- Pacific-North American Region
(180°-30°W, 20°-80°N)
- The empirical orthogonal function (EOF) was applied to linearly detrended summer (winter) 500 hPa geopotential height anomalies [ERA5] from May (November) 1950 through September (March) 2023 (Lee et al. 2019, Millin et al. 2022, Lee et al. 2023)
 - 16 leading Principal Component explains 80% of variance → summer
 - 12 leading Principal Component explains 80% of variance → winter
- The optimal k-means cluster size (k) was determined through intercluster correlation analysis
 - Correlation between each centroid based on the k-means cluster size (Lee et al. 2023)

Summer Weather Regime Classifications

Summer Season Weather Regimes

West Coast Ridge (WCR) [18.11%]

East Pacific Ridge (EPR) [18.15%]

Arctic High (ArH) [19.38%]

Aluetian High (AH) [22.00%]

Arctic Low (ArL) [22.36%]

Winter Weather Regimes

Winter Season Weather Regimes

Alaskan Ridge (AkR) [16.44%]

Arctic High (ArH) [17.39%]

Pacific Trough (PT) [20.59%]

West Coast Ridge (WCR) [21.23%]

Arctic Low (ArL) [24.36%]

Surface Conditions on August 16, 2020 in California

Temperature & Surface Conditions

California Precipitation

12-Month Period

Weather Regimes: Before

Arctic Low (ArL) [22.36%]

July 30 - August 9, 2020 [ArL]

Weather Regimes: During

Arctic High (ArH) [19.38%]

August 16 - August 21, 2020 [ArH]

Weather Regimes: After

Arctic Low (ArL) [24.36%]

November 4 - November 21, 2020 [ArL]

What does this mean for wildfire prediction?

- An above normal significant wildfire potential starting on the June 2020 outlook was outlined for northern CA, NV, and southern OR (NIDIS, 2020) → **important proactive resource**
- **Extreme weather events that aid wildfire development and influence fire behavior currently have low predictions greater than 5-10 days**
- ***A Noblis project aims to leverage AI/ML techniques with subseasonal-to-seasonal (i.e., 2 weeks – 2 months; S2S) weather extreme expertise to build upon foundations of current wildfire modeling and crucial wildfire occurrence resources to enhance predictive models***
 - Weather regime classifications could serve as a S2S predictor

Conclusions & Future Work

- Extremely dry land conditions with lavish vegetation led to increased risk of wildfire fuel prior to the August Complex Fire
 - Prior to the August Complex Fire, ***ArL summer weather regime*** dominated the Rossby wave pattern **two weeks prior** to the extreme event
 - At the onset and the rapid spreading of multiple fires, ***ArH summer weather regime*** dominated from **August 16-21, 2020**
 - Toward the ending of the August Complex Fire, ***ArL winter weather regime*** was present from **November 4-21, 2020**
-
- Future Work: employ AI/ML techniques to simulate the complex land-atmospheric interactions during wildfire cases

Thank You
